**Abstract:** Choledochal cyst is a congenital disease classified in 5 types according to Todani classification and associated to biliary stones, cholangitis, secondary biliary cirrhosis and increased risk of cholangiocarcinoma. The surgical approach ranges from simple cyst excision to complex surgery. Recently, more and more surgeons have started using a minimally invasive approach to treat this disease, mainly for type I and II. We described a totally laparoscopic approach to a Type II choledochal cyst. In addition, a PubMed literature review focusing on laparoscopic surgical resection of choledochal cyst was performed and summarized. We present the case of 25-years-old women with a Type II choledochal cyst diagnosed on Magnetic resonance cholangiopancreatography (MRCP). The patient underwent laparoscopic resection of the cyst and common bile duct followed by Roux-en-Y hepaticojejunostomy without any intraoperative complications. Post-operatively, the patient experienced a bleeding arising from the stapler line of the cul-de-sac of the Roux en Y loop managed conservatively. The patient was discharged at post-operative day-8. Despite the laparoscopic approach is challenging, it has been widely adopted and is now preferred to the open surgery. This approach should be confined to expert centers and performed by skilled hepato-biliary and laparoscopic surgeons.

Keywords: Laparoscopic approach; choledochal cyst; Todani II; hepaticojejunostomy

# Introduction

Choledochal cyst is a congenital cystic dilatation (CCD) of the biliary tree. It may be associated to different hepatobiliary and pancreatic disorders (1). This rare disorder is most common in Asia with two thirds of cases occurring in Japan (2).

Todani classified choledochal cysts into five subtypes including saccular dilatation of the extrahepatic bile duct (Type I), bile duct diverticulum (Type II), choledochocele (Type III), multiples intra and extra hepatic bile dilatations (Type IV), fusiform and saccular cystic dilatation of the intrahepatic bile ducts also known as Caroli's disease (Type V) (3). The type I choledochal cyst is the most common accounting for 67.9% of all subtypes (4). Type II CDC, corresponding to the extrahepatic biliary tree diverticulum, is rare (between 0.8% and 5% of all reported congenital choledochal cyst cases) (5-7).

In most of the cases the diagnosis is done in the childhood, although adult cases have been reported in large series. Due to the malignancy risk a radical resection of the cyst with Roux-en-Y hepatico-jejunostomy is mandatory (8,9). Laparoscopic approach is becoming more and more widely adopted.

# Methods

We describe a case of totally laparoscopic approach to type

Page 2 of 8

II choledochal cyst and we provide the video of the surgery (*Video 1*). In addition, a PubMed literature review focusing on laparoscopic surgical resection of choledochal cyst was performed.

# **Case report**

## Clinical bistory

A 25 years old woman was referred to our Institute for long

lasting abdominal pain. Abdominal ultrasound showed the presence of a hilar cystic lesion with apparently absence of gallbladder. MRCP findings were in favor of diagnosis of Todani 2 choledochal cyst but the communication between the cystic lesion and bile duct was not detected (Figure 1). Endoscopic ultrasound (EUS) confirmed the diagnosis of a 28-mm Type II choledochal cyst located in the middle part of bile duct. Accordingly, EUS didn't show any communication between the choledochal cyst and the choledochus, probably due to a short and very narrow neck of the cystic lesion. No anomalies of bilio-pancreatic junction were detected. Liver tests were all normal. After discussion in our multidisciplinary meeting (MDT), a laparoscopic resection of the cvst, eventually extended to the bile duct, and Roux-en-Y hepaticojejunostomy were scheduled.

# **Operative** technique

Under general anesthesia, the patient was placed in French position. The surgeon standed between the patient's legs, the first assistant was on the right of the patient and the second assistant, as well as the nurse scrub, were placed on the left of the patient. The procedure required five ports. The pneumoperitoneum was inflated through a 12-mm midline port, which will be used to place the camera, approximately 2 cm above the umbilicus. Two 10-mm ports were placed on the mid-clavicular line of both sides, 1 cm cranial to the camera port. A 5 mm epigastric port was placed under the xiphoid process. One additional port will be inserted later to realize the anastomosis on the left flank (*Figure 2*). The table was placed in reverse Trendelenburg position to facilitate displacement of the transverse colon and small bowel from the operative field.

The choledochal cyst was located on the right part of the hilum, affecting the medial third of the common bile duct very close to the gallbladder (*Figure 3*). Surgery began with complete dissection of structures within Calot triangle. Once identified and partially cut the cystic duct, we realized an intraoperative cholangiography showing a non-dilated common bile duct and absence of communication with the cystic lesion probably because of a short, edematous and inflamed neck. After completed the cholecystectomy, the gallbladder was stored in an endo-bag and then extracted.

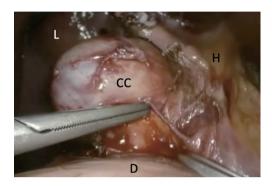

We performed a very gently dissection of the common hepatic duct and the choledochus using bipolar forceps and scissors. We tried to free the cyst from the bile duct with no success, as the cyst was very inflamed and subsequently

### Laparoscopic Surgery, 2020

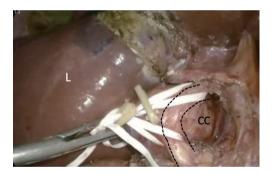

completely stack to the bile duct. We hence decided to realize an "en-bloc" resection of the cyst and the bile duct.

We encircled the common hepatic duct and the choledochus with a first tape upstream and a second one downstream the borders of the cystic lesion (*Figure 4*).

After being completely dissected and freed from the

**Figure 3** The choledochal cyst located on the right part of the hilum. CC: choledochal cyst, L: Liver, H: hilum, D: duodenum.

**Figure 4** Common bile duct and the choledochus are encircled with a tape. CC: choledochal cyst, L: liver, ---: Bile duct.

hilum, the choledochus was stapled with a linear EndoGIA<sup>®</sup> (*Figure 5*) while the common hepatic duct was cut with the scissors. The specimen was removed through an extension of the 10 mm right port incision using a lap bag.

To realize a Y-en-Roux hepatico-jejunostomy the jejunum was divided at 60 cm distal to the Treitz ligament using an EndoGIA<sup>®</sup> linear stapler. The limb was then pulled through an opening created in the mesentery of the transverse colon.

Hepaticojejunostomy was performed in an end-to-side fashion using absorbable running suture (*Figure 6*). Jejuno-jejunostomy was realized using an EndoGIA<sup>®</sup> stapler.

A suction drain was left in the Morrison space. Fascia of extraction incision and ports sites  $\geq 10$  mm were closed and all skin incisions closed with subcuticular suture. Operation time was 360 minutes. Post-operatively, the patient experienced a bleeding arising from the stapler line of the cul-de-sac of the Roux en Y loop managed conservatively. Abdominal drain was removed at postoperative day 2.

Postoperative CT-scan was normal, and the patient was discharged at post-operative day 8.

Histopathological analysis confirmed the diagnosis of choledochal cyst with low-grade dysplasia and no evidence of malignancy.

# Discussion

The typical presentation of choledochal cyst, including abdominal pain and jaundice has been reported only in 6% of cases, although cases of unusual presentation have been described. CDCs are more frequent in females with 3:1 ratio (10).

CDCs are frequently associated with pancreaticobiliary maljunction (PBM). PBM is a congenital anomaly defined as

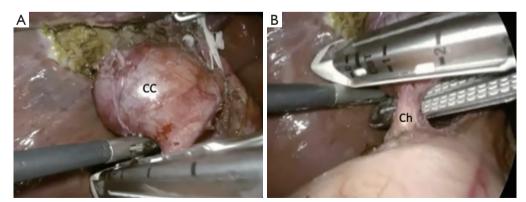

Figure 5 Choledochus is sectioned with a stapler. (A) CC: choledochal cyst; (B) Ch: choledochus.

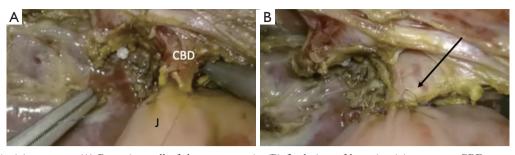

Figure 6 Hepaticojejunostomy. (A) Posterior wall of the anastomosis; (B) final view of hepatico-jejunostomy. CBD, common bile duct; J, jejunum; arrow, hepatico-jejunostomy.

a junction of the pancreatic and the bile ducts located outside duodenal wall with as a long common channel (>10 mm). As the pancreatic duct pressure is higher than the one in the bile duct, pancreatic juice can leak back in to the common bile duct leading to inflammation of the biliary epithelium and potential biliary carcinogenesis (5).

Symptoms of choledochal cyst differ according to the period of presentation. In children jaundice is the most common symptom while adults usually present other symptoms. Cystic stones are described in 49% of cases, followed by cholangitis (32%), acute pancreatitis (10%) and chronic pancreatitis (2%) (6,11).

Due to the risk of cholangiocarcinoma development (3%) cyst resection is mandatory followed by hepaticojejunostomy, choledochojejunostomy or hepaticoduodenostomy (12).

The first case of laparoscopic choledochal cyst resection has been described in 1995 by Farello (13) and safety and feasibility have been confirmed thereafter. Miniinvasive approach has a lot of advantages over laparotomy including small incisions, magnification of the surgical field, less intraoperative bleeding and abdominal wall complication (1,14).

Laparoscopic biliary surgery is not widely adopted because of the complexity of the procedure and the need of skilled surgeons (14,15).

An extensive review of the literature was conducted with 12 publications of large case series and retrospective studies being identified and reviewed. Among them four are comparative studies, being the rest single center noncomparative (*Table 1*). As expected, there are no prospective studies.

Liu *et al.* showed that compared with open operation, the total laparoscopic approach had a longer operative time  $(249\pm58 vs. 132\pm15 min with open approach)$  (1). The importance of learning curve has been clearly showed by their results as the laparoscopic operative time decreased

significantly to 190 min after the first 20 cases.

This concept has been confirmed by Aly *et al.* in 2017 (21). In their series of 36 patients with CCDs laparoscopically treated, they reported an early- and late post-operative complication rate respectively of 19% and 5%. In 3 patients an emergency laparoscopic re-do surgery was needed. Authors also compared results from the former period with those from the latter period showing less operative blood loss, open conversion rate and hospital stay in the last period underlying the importance of learning curve in a such complicated surgery.

A morbidity rate of 20% and a mortality rate of 3.3% have been reported by Tian *et al.* in a series of 60 adult patients who underwent laparoscopic surgery (18).

The most common complications reported by Jang *et al.* in a series of 82 patients were minor biliary leakage (7%) and fluid collection (2.5%), both managed conservatively (17).

In a series of 110 patients (55 adults and 55 children), Senthilnathan *et al.* reported an overall complication rate of 10% with a re-exploration rate of 1.81% and 1 postoperative death due to acute severe pancreatitis with multiorgan failure (14). Authors showed that laparoscopic approach to choledochal cyst is safe and feasible. Well known benefits of minimal invasive surgery such as magnification of surgical view, less intraoperative bleeding, better control of post-operative and better cosmetic results have been also found in the surgical scenario.

Shorter hospital stay is another advantage of minimal invasive approach compared to open surgery, as showed by Lü *et al.* (16).

No difference in term of morbidity and mortality rates has been found between the two surgical approaches (15). Authors suggested to leave a proximal cuff of the cyst in order to make the hepatico-jejunostomy anastomoses easier.

A post-operative complication rate of 22.4% has been reported by Lee *et al.*, being the biliary leakage the most

hepaticojejunostomy

#### Laparoscopic Surgery, 2020

common (7.14%) (24). In this paper, authors compared totally laparoscopic versus laparoscopic dissection followed by robotic hepatico-jejunostomy and they concluded that robotic surgery allows for more precise and secure sutures during anastomosis, thereby reducing biliary complications.

Another paper comparing robotic versus laparoscopic approach found no difference in terms of complications (22). Authors managed to shorten operative time by performing extracorporeal jejuno-jejunostomy. Thereby there are some advantages by using robotic approach, such as better intracorporeal suturing and provision of a good 3D visual field.

Hwang *et al.* underlined the importance of the learning curve in such complex surgery and suggested that laparoscopic approach will eventually become an advantageous treatment option for selected patients (20). In their series, laparoscopic excision of choledochal cyst was attempted in 20 patients with a conversion to laparotomy rate of 35% due to: bleeding, Roux loop venous congestion, abdominal obesity and severe fibrosis and inflammation around the cyst. Authors reported a mean operative time of 398.8±58.7 min and a mean postoperative hospital stay of 9.3 days.

Biliary complications were the most common complications after laparoscopic approach to CCDs also in the series of 67 patients, mainly adults, published in 2016 by Moslim *et al.* (25).

Our case report concerns a Type II choledochal cyst diagnosed in a 25-years-old patient.

Type II CCD, defined as extrahepatic bile duct diverticulum, is rare (between 0.8% and 5% of all reported CCDs cases). At the time of writing, the biggest series (19 patients) of Type II CCD surgically treated, is the European Multicenter Study of the French Surgical Association, being the others reports only single cases or small series (26). In the French multicenter study, all patients underwent choledochal cyst resection despite the extrahepatic bile duct has been resected in only 11 patients (57.9%).

Laparoscopic approach was attempted in three patients but due to technical difficulties and bile duct injury surgeons were obliged to convert in all cases.

In our case, we associated a bile duct resection as we found the hepatic pedicle to be inflamed and this did not allow separating the choledochal cyst from the biliary duct.

We managed to complete the surgery laparoscopically despite a challenging hepaticojejunostomy due to the small size of the proximal bile duct stump.

e

# Conclusions

Laparoscopic resection of choledochal cyst with hepaticojejunostomy is safe and feasible based on our case and review of the literature. Patients have shorter hospital stay and outcomes are comparable to the open approach.

Operative time is longer but decreases with the learning curve. Due to the technical difficulties it should be performed in reference centers by surgeon with experience in laparoscopic and biliopancreatic surgery.

Patients should be followed at long term in order to detect late complications and malignancy.
