**Background:** The effects of metformin and sulfonylurea on new-onset cognitive dysfunction in type 2 diabetes mellitus (T2DM) remain unclear. This study aimed to compare the risks of dementia and anxiety disorder and depression between metformin and sulfonylurea users.

**Methods:** This retrospective cohort study included patients with T2DM in Hong Kong between 1<sup>st</sup> January 2013 and 31<sup>st</sup> December 2019. The primary outcomes were new-onset dementia and new-onset anxiety disorder and

depression. The secondary outcome was all-cause mortality. Patients >18 years old with metformin or sulfonylurea use were included. Patients with prior diagnoses of the above events or relevant medications usage were excluded. 1:1 propensity score matching was performed based on demographics, prior comorbidities, use of other medications, and laboratory tests.

**Results:** After 1:1 propensity score matching, the final study cohort consisted of 21,244 matched metformin users (45.2% male, mean age: 67.9±12.0 years) and 21,244 sulfonylurea users (49.6% male, mean age: 66.8±13.7 years). The overall mean follow-up time was 4.33±1.79 years. Metformin use was associated with lower risks of dementia [hazard ratio (HR): 0.88; 95% confidence interval (CI): 0.80–0.97, P=0.0074], anxiety disorder and depression (HR: 0.71, 95% CI: 0.61–0.82, P<0.0001), and all-cause mortality (HR: 0.83, 95% CI: 0.80–0.85, P<0.0001) than sulfonylurea use. These associations remained significant in the sensitivity analyses with cause-specific hazard models and sub-distribution hazard models.

**Conclusions:** The use of metformin was associated with lower risks of dementia, anxiety disorder and depression, and mortality than sulfonylurea use in patients with T2DM.

**Keywords:** Metformin; sulfonylurea; cognitive dysfunction; mortality; diabetes mellitus; type 2
