Background: This study was to systemically analyze the mechanism of LXR ligand GW3965-induced sensitivity to EGFR-TKI in EGFR-TKI-resistant non-small cell lung cancer (NSCLC) cell lines.

Methods: Gefitinib-resistant PC9 cell line (EGFR exon 19 deletion) was treated with single and combined treatment with GW3965 and gefitinib. Cell viability, apoptosis and autophagy were detected using MTT, flow cytometric analysis and immunofluorescent analysis, respectively. Autophagy-related signaling pathways were detected using Western blot analysis.

Results: Inhibited cell viability by single and combined treatment with gefitinib and GW3965 were observed. Combined treatment with gefitinib and GW3965 increased LC3 II/I ratio and Beclin 1 expression. Synergistic effect of gefitinib and GW3965 on apoptosis and autophagosome accumulation as well as on the inhibition of Akt/mTOR signaling and activation of AMP-activated protein kinase (AMPK) was observed in gefitinib-resistant PC9 cells. AMPK expression showed similar profile with apoptosis and autophagy of PC9 cells.

Conclusions: We confirmed that GW3965 and gefitinib showed synergistic effect on Akt/mTOR inhibition, apoptosis and autophagy of lung cancer cells. Gefitinib sensitivity in PC9 cell line might be mediated by Akt/mTOR, AMPK and JNK signaling pathways.

Introduction

Non-small cell lung cancer (NSCLC) is a prominent cause of cancer-related deaths. The introduction of epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (EGFR-TKIs), including erlotinib and gefitinib, is the most significant advance in the treatment of NSCLCs. Single-agent treatments with EGFR-TKIs have been shown to significantly improve outcomes of patients with NSCLC harboring EGFR specific mutations compared

with chemotherapy (1-3). Unfortunately, almost all patients who initially responded to EGFR-TKIs finally developed resistance (4), and their prognosis remains poor. Acquired resistance to gefitinib might involve T790M mutations, hepatocyte growth factor (HGF) over-expression, compensatory MET overactivity and loss of PTEN (5-8).

Autophagy is a highly conserved self-digesting process in cells, which is considered to be closely linked to both tumorigenesis and chemoresistance. There are increasing

evidences showing that autophagy plays important role in resistance to EGFR-TKIs. EGFR inhibitors can induce autophagy, but the specific role of the induction of autophagy remains controversial (9). Recent work has demonstrated that upregulated autophagy is involved in resistance to EGFR-TKIs, including gefitinib (10,11) and erlotinib (12,13). Moreover, blocking autophagy can increase sensitivity of resistant cancer cells to EGFR-TKIs. On the contrary, there are also some data suggesting that a low level of autophagy is strongly linked to EGFR-TKIs resistance, and the combination of EGFR-TKIs with autophagy inducer may sensitize EGFR-TKI-resistant cancer cells to EGFR-TKIs (14-17). Thus, autophagy regulation may be a viable strategy to conquer the treatment of lung cancers with resistance to EGFR-TKIs.

Liver X receptors (LXRs) play crucial roles in glucose metabolism and the modulation of inflammatory responses. There are increasing evidence showing the association and potential efficacy LXRs and their ligands, including synthetic ligands T0901317 and GW3965, with malignancies. As reported, LXR ligands were shown to have antiproliferative effects on a variety of cancer cell lines (18-22). Several previous studies had proven that LXR agonists promoted cancer cell death through reduction of PI3K or AKT activity via EGFR downstream pathways (23,24). What's more, it had been reported that treatment with LXR agonists could inhibit Akt activation and reverse gefitinib-resistance in NSCLC cell lines (25,26). As we all known, there is a close relationship between the changes of autophagy and the expression of PI3K/AKT signaling. Previous studies had shown that gefitinib-induced cell autophagy and apoptosis was mediated by PI3K/Akt inactivation, and GW3965 had synergistic effect on gefitinib in gefitinib-resistant in cancer cells (25,27). However, there was no systemic analysis showing the association of LXR ligand GW3965-induced autophagy and apoptosis with EGFR-TKI in EGFR-TKI-resistant NSCLC cell lines.

To clarify the association of GW3965-induced autophagy and apoptosis with EGFR-TKI in EGFR-TKI-resistant NSCLC cell line, we designed *in vitro* experiments to investigate the effects of GW3965-induced autophagy on the development of gefitinib resistance in NSCLC cell line PC9. We firstly established the gefitinib-resistant PC9 cell lines, and treated cells with single and combined treatments with gefitinib and GW3965. Cell autophagy and apoptosis were detected to evaluate the effect of both single and combined treatments. We are confident that with these experiments we will be able to provide new insights into

overcoming the chemotherapy resistance to EGFR-TKIs in NSCLC cells.

Methods

Cells, antibodies, and reagents

The human NSCLC PC9 cell line (EGFR exon 19 deletion, Del E746-A750) was obtained from the central laboratory of Shanghai Pulmonary Hospital, and was maintained in RPMI-1640 (Hyclone, Logan, UT, USA) supplemented with 10% FBS (Hyclone, Logan, UT, USA) at 37 °C, with 5% CO₂. Gefitinib (ZD1839) was purchased from Selleck (Selleck Chemicals, TX, USA), GW3965 was obtained from Sigma-Aldrich (Sigma-Aldrich; Merck KGaA, Darmstadt, Germany). RIPA buffer, 3-(4,5-Dimethyl thiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) solution and β-actin antibody was obtained from Sigma-Aldrich (Sigma-Aldrich; Merck KGaA, USA). Propidium iodide (PI) was obtained from Beijing Beyotime Company (Beijing, China) and acridine orange (AO) was purchased from Solarbio (Beijing, China). The Annexin V-FITC Apoptosis Detection Kit was obtained from BD Biosciences (San Jose, CA, USA). Primary antibodies against total (t)-Akt (#4691, 1:1,000), phosphor(p)-Akt (#9611, 1:1,000), t-AMPK (#5831, 1:1,000), p-AMPK (#2535, 1:1,000), t-mTOR (#2972, 1:1,000), p-mTOR (#2971,1:1,000), t-p70s6k1, p-p70s6k1, Beclin-1 (#3738, 1:1,000) and LC3 (#2775, 1:1,000) were purchased from Cell Signaling Technology (Beverly, MA, USA). Immunofluorescence antibody LC3 II was obtained from Abcam (Cambridge, UK, USA). Trypsinization (Biosharp Co., China), SDS-PAGE, (Sigma-Aldrich, St Louis, MO, USA), PVDF membranes were purchased from Bio-Rad Laboratories, USA. Secondary antibodies including HRP-conjugate goat anti-rabbit IgG and goat anti-mouse IgG were obtained from Abcam. N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) was purchased from Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China).

Cells, culture conditions, and establishment of gefitinib-resistant PC9 cell line

Gefitinib-resistant PC9 cell line was generated by exposing to RPMI-1640 medium containing 2.5 μg/mL MNNG for 24 h, and culturing in RPMI-1640 medium supplementing with 0.2 μM gefitinib for 7 days according to previously described methods (26). Cells were then maintained in gefitinib-free medium until 90% confluence, followed

by incubation with 0.3–0.5 μM gefitinib for 21 days for subcloning. Single colonies were obtained by trypsinization. The cell line was maintained in medium consisting of 0.05 μM gefitinib at 37 °C, with 5% CO_2 , and verification of integrin $\beta 1$ expression was conducted by Western blot and PCR analyses, while no T790M mutation occurred (28).

Analysis of cell viability

The inhibitory effect of gefitinib on cell proliferation was detected using the MTT assay. PC9 cells were seeded into 96-well plates for 24 h prior to exposing to gefitinib and GW3965. Cells were incubated by drugs for 48 h, followed by incubation with 5 mg/mL MTT solutions at 37 °C for 4 h and 50 μL of DMSO. Finally, plates were detected using a microplate reader (Multiskan MK3; Thermo Labsystems, Helsinki, Finland) at 570 nm, and the inhibition ratio was calculated using the following formula: Inhibition ratio (%) = $[\text{OD}_{570\text{nm}}(\text{test}) - \text{OD}_{570\text{nm}}(\text{control}, 0 \mu\text{M})] / \text{OD}_{570\text{nm}}(\text{control}) \times 100\%$. All experiments were performed at least in three replications.

Western blot analysis

PC9 cells were incubated with single or combined GW3965 and Gefitinib for 48 hour. Cellular proteins were isolated with RIPA buffer. For immunoblotting, cell lysates were separated with 10% SDS-PAGE and then were transferred onto PVDF membranes, which were then blocked with 5% non-fat milk at room temperature for 1 h. Incubation with primary antibodies against LC3 II/I, Beclin-1, total Akt, p-Akt, total AMPK, p-AMPK, mTOR, p-mTOR, p70S6K1, and p-p70S6K1 were performed at 4 °C overnight, followed by secondary incubation in HRP-conjugated secondary antibodies [goat anti-rabbit (1:20,000); anti-mouse (1:4,000) IgG] at room temperature for enhanced chemiluminescence (ECL). NIH ImageJ software (<http://rsb.info.nih.gov/ni-image/>) was used for immunoreactive bands analysis.

AO staining

Cells were treated with different drugs for 48 h and then AO staining was performed. For AO staining, prepared cells were stained with 0.01% AO in dark at 37 °C for 15 min and then cells were washed with serum-free media. A Leica fluorescence microscope (Leica, Wetzlar, Germany) was employed for the visualization of fluorescent staining cells. With using 492 nm blue excitation light, the green (510–

530 nm) and red (>650 nm) fluorescence emission from cells was visually examined under a fluorescence microscope. The autophagy cell rate (%) was calculated as the percentage of positively stained cells for three fields (containing at least 50 cells per field) for each experimental condition.

Apoptosis analysis

Cell apoptosis was determined using Annexin V-FITC Apoptosis Detection Kit according to the manufacturer's protocol. Cells in 24-well plates were precultured for 24 h, and then treated with different drugs for 48 h at 37 °C with 5% CO_2 . Then, 5 μL of solutions were added into the cell cultures for 15 min in dark. Annexin V+ apoptotic cell percentage was detected using a FACS Calibur flow cytometer (BD Biosciences).

Statistical analysis

At least in triplicates were performed for all cellular experiments. Averaged data was presented as mean \pm standard deviation (SD). GraphPad Prism 6 software (GraphPad Software Inc., La Jolla, CA, USA) was used for data statistical analyses. A one-way analysis of variance (ANOVA) and *t*-test was used for the analysis of differences among and between groups, respectively, with significant criteria of P value less than 0.05.

Results

Cell viability analysis

Figure 1 shows the influence of GW3965 and gefitinib on the cell viability of gefitinib-resistant PC9 cell line. The cell viability was gradually inhibited by GW3965 or gefitinib single and combined treatments, especially at $\geq 20 \mu\text{M}$ concentrations ($P < 0.05$). Since treatment of the cells with 5 μM GW3965 had no significant effects on cell viability, we used this concentration for further analysis. Gefitinib induced higher inhibition ratio when there was GW3965 (at $\geq 20 \mu\text{M}$). Increment in cell viability inhibition ratio was observed in GW3965 (5 μM) in combination with gefitinib treatment ($\geq 1 \mu\text{M}$) compared with gefitinib single treatment ($P < 0.05$). These data suggested GW3965 overcame the obtained gefitinib-resistance in PC9 cells. With combination of GW3965 (5 μM), the half maximal inhibitory concentration (IC_{50}) of gefitinib was 20 μM . Subsequent experiments were carried out at this concentration.

Cell autophagy analysis

Figure 2A and B show the effect of single and combined treatments with GW3965 and gefitinib on cell autophagy. Single treatments with GW3965 or gefitinib alone did not influence the LC3 II/I ratio and expression of Beclin 1 protein ($P > 0.05$ vs. control, Figure 2A and B). The combination of them, however, significantly upregulated

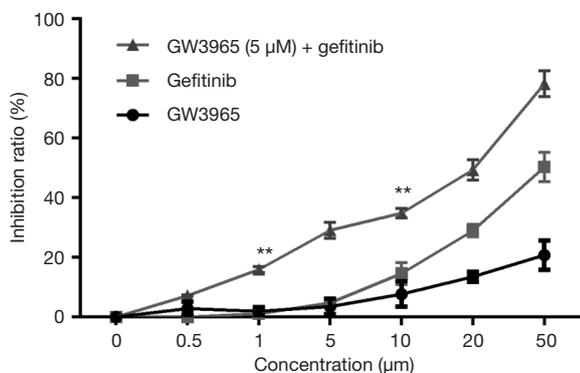

Figure 1 Inhibitory effect on cell viability. Cells were treated with drugs at different concentrations for 48 h and the cell viability was determined by the MTT assay. Inhibition ratio of cell viability was calculated as: $[\text{OD}_{530\text{nm}}(\text{test}) - \text{OD}_{530\text{nm}}(\text{control}, 0 \mu\text{M})] \times 100\% / \text{OD}_{530\text{nm}}(\text{control})$. Gefitinib showed IC_{50} at the dose of 20 μM when co-treated with GW3965 (5 μM). Data are shown as mean \pm standard deviation of three independent experiments. **, $P < 0.01$ vs. GW3965 at the same level.

LC3 II/I ratio and Beclin 1 protein fold change compared with control ($P < 0.01$), showing the synergistic effect of GW3965 and gefitinib on activating the expression of autophagy related protein.

Autophagy is featured by the formation of autophagosomes and autolysosomes. To further confirm the accumulation of amphisomes and autolysosomes in gefitinib-resistant PC9 cell line, we conducted the AO staining analysis. As shown in Figure 3, GW3965 single treatment significantly increased AO staining in acidic vesicular organelles in PC9 cells ($P < 0.05$), but treatment with gefitinib alone showed no obvious change (Figure 3A,B). Moreover, when treated with combination of GW3965 and gefitinib, the number of AO-stained cells increased dramatically in comparison with that of control cells and treatments with GW3965 or gefitinib alone.

Taken together, these results suggested that GW3965 could significantly increase the autophagy level in gefitinib-resistant PC9 cell line with combined treatment with gefitinib.

Apoptosis analysis

Figure 4A shows the result of cell apoptosis analysis using flow cytometric analysis. Obviously increased apoptotic cell percentages were found in cells treated with single (Gefitinib 7.64 ± 0.27 ; GW3965 7.23 ± 0.38) and combined agents (13.52 ± 0.60) in comparison with control (0.22 ± 0.03 ; $P < 0.001$, Figure 4B). Difference was observed between

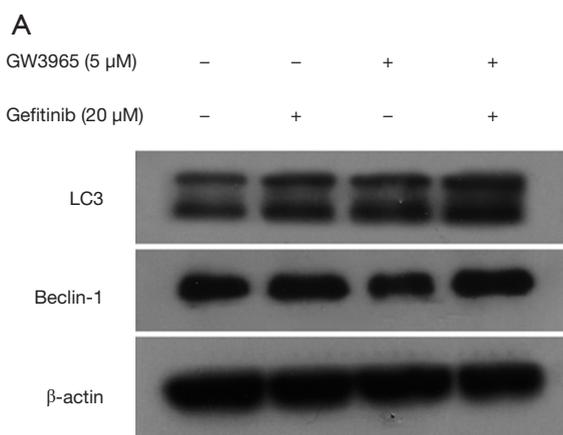

Figure 2 Effect of GW3965 (5 μM) and gefitinib (20 μM) on cell autophagy of gefitinib-resistant PC9 cell line. The cell lysates were harvested and autophagy-related proteins were analyzed by Western blotting. (A) The Western blotting of the LC3 II/I and Beclin 1 protein; (B) densitometry analysis of Western blots shows quantitation of LC3 II/I and Beclin 1. **, $P < 0.01$ (vs. control); # and ##, $P < 0.05$ and 0.01, respectively.

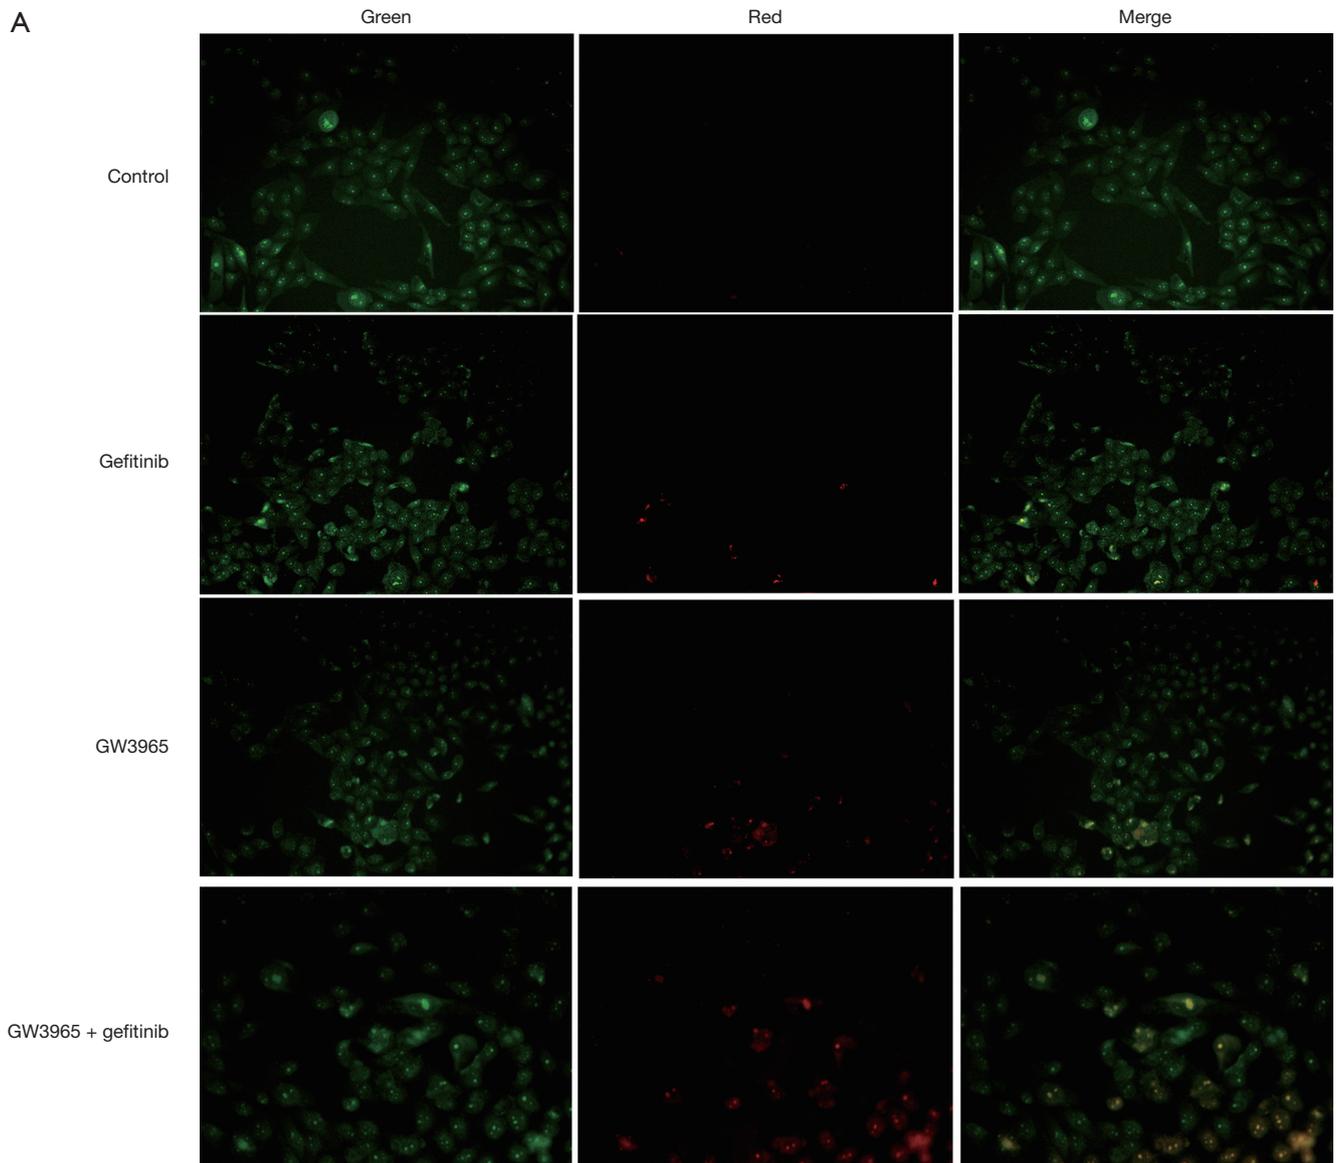

Figure 3 Fluorescence analysis of acridine orange staining in gefitinib-resistant PC9 cell line. (A) Green staining reflects the background and red or orange staining occurs in acidic (autophagic) vacuoles. Magnification $\times 400$; (B) the percentage of positively stained cells in different treatments. * and **, $P < 0.05$ and $P < 0.01$ vs. control, respectively; #, and ##, $P < 0.05$, and $P < 0.01$, respectively.

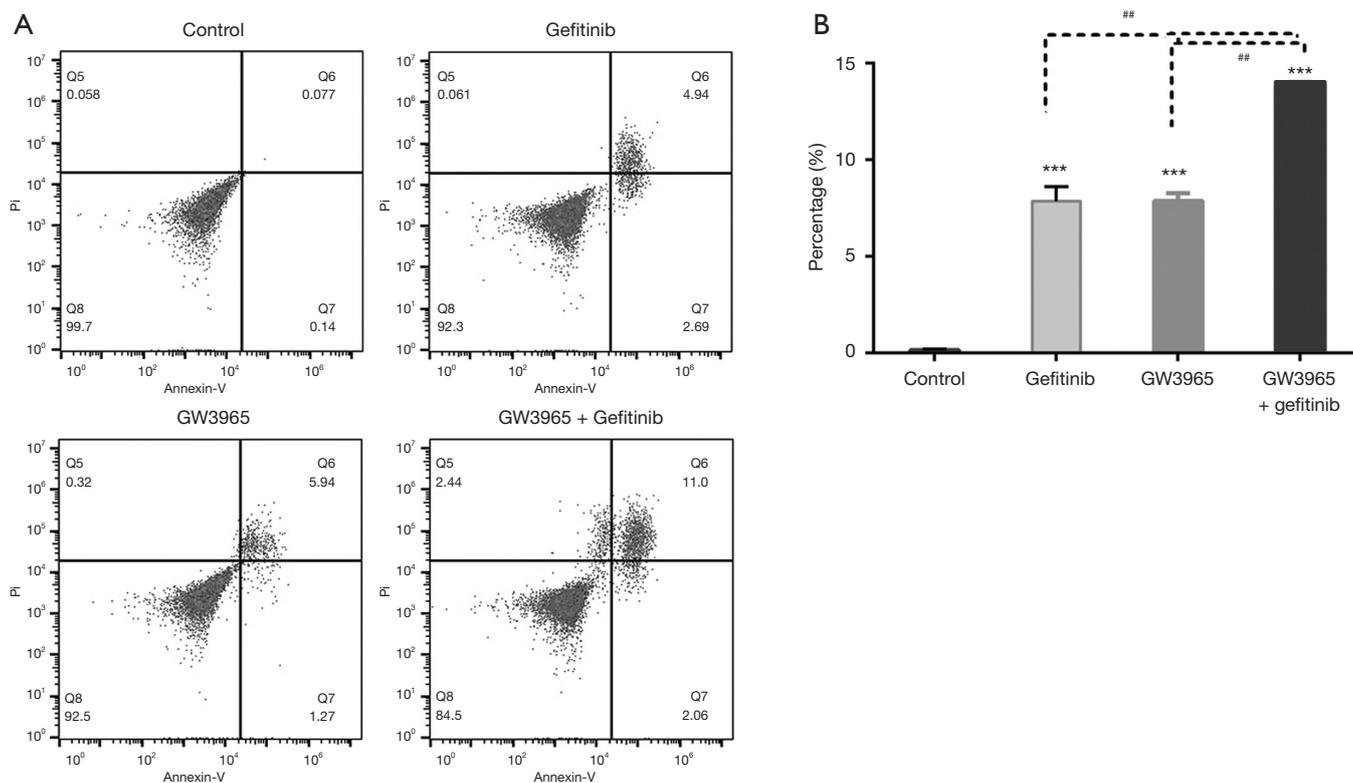

Figure 4 Flow cytometric analysis of apoptotic cells. Annexin V-PE staining kit was used, and Annexin V+ apoptotic cell percentage was calculated. (A) PC9 cells were treated with Gefitinib (20 μ M) and GW3965 (5 μ M) or alone, for 48 h; (B) changes of cell apoptosis after drug treatment. single and combination drug treatments ($P < 0.01$; Figure 4B). These results revealed that gefitinib (20 μ M) and GW3965 (5 μ M) single treatments increased the apoptosis of gefitinib-resistant PC9 cells, and GW3965 (5 μ M) additional administration enhanced the effect of gefitinib (20 μ M).

The effect of GW3965 and gefitinib on AMPK/Akt/mTOR signaling axis

Figure 5 shows the effect of GW3965 and gefitinib drug treatments on the expression of AMPK-mediated Akt/mTOR signaling axis. Synergistic effects of GW3965 and gefitinib on the inhibition of Akt, mTOR and AMPK expression were observed. Gefitinib and GW3965 single treatments upregulated p-AMPK ($P < 0.001$), decreased p-Akt and p-mTOR ($P < 0.05$), and the combination treatment enhanced all changes ($P < 0.001$, Figure 5A,B). In comparison with gefitinib single treatment, significantly lower p-Akt and p-mTOR level ($P < 0.001$) and higher

p-AMPK level ($P < 0.05$) were detected in cells under combination treatment with gefitinib and GW3965 (Figure 5A,B). We demonstrated that there were synergistic effects between gefitinib and GW3965 on activation of AMPK-mediated Akt and mTOR inhibition.

No enhanced downregulation was observed in p-p70S6K1 expression in cells with combination treatment comparing with gefitinib alone ($P > 0.05$, Figure 5B). Moreover, the expression profile of p-AMPK protein was consistent with the apoptosis level in gefitinib-resistant PC9 cell line (Figures 4,5). In addition, we found that gefitinib and GW3965 single treatment decreased and increased p-p70S6K1 expression in PC9 cells, respectively, with contrary profiles to apoptosis and autophagy.

Discussion

Drug combinations have been widely used in treating complex diseases such as cancer. Several possible mechanisms have been proposed. For example, the parallel pathway

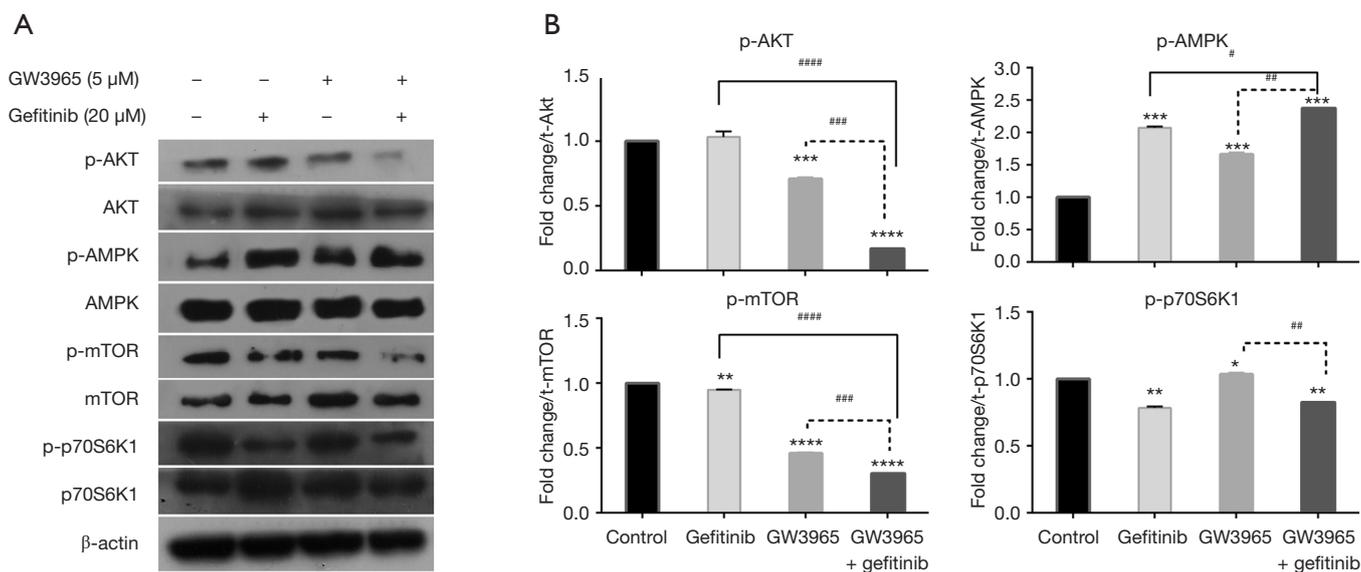

Figure 5 Western analysis of the related signaling pathways. (A) Protein expression levels in the cell lysates were determined by Western blotting; (B) densitometry analysis of Western blots shows quantitation of proteins. *, **, *** and ****, $P < 0.05$, 0.01, 0.001, and 0.0001 vs. control, respectively. #, ##, ###, and ####, $P < 0.05$, 0.01, 0.001, and 0.0001, respectively.

inhibition model suggested that two drugs will be synergistic if they inhibit two proteins on parallel pathways essential for an observed phenotype (29). The mechanism of drug synergy is very complicated and their activities are highly dynamic. Our study demonstrated that both GW3965 and gefitinib could inhibit cell proliferation in gefitinib-resistant PC9 cell line. GW3965 and gefitinib induced cell autophagy and apoptosis, and activated AMPK-mediated Akt/mTOR signaling axis *in vitro*. We confirmed that the synergistic effect of GW3965 and gefitinib on the AMPK activation and inhibition of Akt/mTOR signaling axis and the promotion of cell autophagy and apoptosis in PC9 cells.

Elevated EGFR expression level has been identified as a prominent marker of various cancers, and it appears to confer solid and metastatic types, including NSCLC (30-33). EGFR mutations are dominant factors for the resistance and response to TKI therapy in NSCLC (1,3,34). EGFR modulates the proliferation, apoptosis, autophagy, migration and angiogenesis of cancer cells, which are essential for cancer growth, migration, solid growth and metastasis (10,13,16,30). Among these cellular behaviors, autophagy serves as a protective effect for EGFR-TKI resistance, although induced hyperautophagy is a beneficial therapeutic strategy for cancers (13,16).

It has been reported that EGFR-TKI induces autophagy

and apoptosis in sensitive NSCLC lines, but not in resistant NSCLC lines (13,16,27). Zhao *et al.* reported that there was no response to gefitinib (500 nM) in gefitinib-resistant A549 cells (27). Gorzalczy *et al.* reported that H1299 cells showed a low level sensitivity to erlotinib (5 μ M), while the administration of autophagy inducer rapamycin overcame it, showing enhanced sensitivity in H1299 cells to EGFR-TKI erlotinib (16). Li and his colleagues showed that erlotinib (0.1 μ M, 0.2 μ M) only induced autophagy in NSCLC sensitive cell lines (HCC827 and HCC4006, EGFR exon 19 del), but not in resistant cell lines (H358, wild type, and H1975 L858R/T790M) (13). In contrast, Li *et al.* enhanced cell sensitivity in NSCLC sensitive cell lines using an autophagy inhibitor chloroquine. In addition, they found the silencing of autophagy genes ATG5 and Beclin 1, which blocks the autophagy in sensitive cells, promoted cell sensitivity (13). These studies demonstrated that both inhibited and excessive elevated autophagy enhanced cancer cell sensitivity. In our present study, we detected the inhibited cell proliferation and increased apoptosis by gefitinib treatments (20 μ M) in gefitinib-resistant PC9 cells. Consistent with previous studies, no significant autophagy changes were observed in our study.

Previous studies had shown that gefitinib-induced cell autophagy and apoptosis in NSCLC cells was associated with the activation of AMPK signaling pathway and

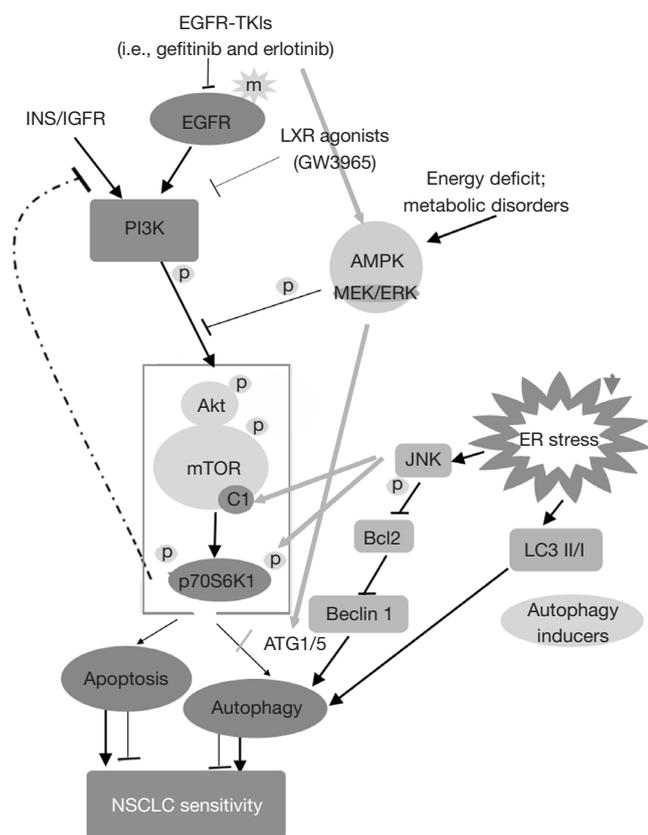

Figure 6 The potential interaction between AMPK and PI3K mediated signaling pathways for autophagy regulation. p, notes phosphorylation. m, represent mutations of EGFR. ERFR-TKI-mediated downstream pathway inhibition was essential for gefitinib induced autophagy in NSCLC cells. AMPK could inhibit PI3K/ Akt signaling pathway and activate ATG1 to trigger autophagy. Inhibition and over upregulation of autophagy both induce sensitivity to gefitinib. The signalings indicates by blue lines and the JNK signaling might the potential roads responsible for gefitinib-induced apoptosis and autophagy in gefitinib-resistant PC9 cell line. EGFR, epidermal growth factor receptor; NSCLC, non-small cell lung cancer.

inhibition of PI3K/Akt-mTOR signaling pathway (15,27). The hyperactivation of PI3K/Akt-mTOR signaling axis is prominent for tumor growth, proliferation, autophagy and survival and is common in cancer cells (23,27,35,36). The inhibition of AMPK, however, restored gefitinib-induced autophagy (15). AMPK is an energy-sensor which is activated by increased AMP/ATP(ADP) ratio, and is important for the induction of cell autophagy (37,38). AMPK triggers autophagy by directly activating ATG1

(ULK1) or inhibiting downstream PI3K/Akt-mTOR signaling pathway (Figure 6) (39,40). In addition, mTORC1-mediated inhibition of ATG1 was essential for autophagy regulation (41). In our present study, we demonstrated that gefitinib treatment induced p-AMPK expression, and inhibited p-Akt and p-mTOR expression, suggesting the inhibition of EGFR-PI3K/Akt-mTOR signaling pathway and upregulation of AMPK by gefitinib.

Several studies have proven that LXR agonists promoted cancer cell death and reserved gefitinib-resistance in NSCLC cell lines through inhibition of PI3K/AKT pathway downstream of EGFR (23-26). The synergistic effect of LXR ligands T0901317 and GW3965 on gefitinib have been reported in gefitinib-resistant NSCLC cells (25). T0901317 and GW3965 sensitized HCC827-8-1 cells to gefitinib by inhibiting Akt activation and enhancing cell apoptosis (25). In our present study, we demonstrated that GW3965 showed synergistic effects on gefitinib-inhibited PI3K/Akt-mTOR signaling pathway, enhanced AMPK activation, cell apoptosis and autophagy. These suggested GW3965 administration might overcome the acquired resistance to gefitinib in PC9 cell line. We found that the autophagy in PC9 cells was consistent with AMPK, and the apoptosis level was contrary to Akt/mTOR activation, respectively. These might demonstrate that the induced autophagy and apoptosis in gefitinib-treated cells was mediated by AMPK-ATG1/ULK1 activation and p70S6K1 inhibition (Figure 6), which was responsible for enhancing sensitivity to gefitinib in PC9 cells.

P70S6K1 is a substrate of mTORC1. c-Jun N-terminal kinase (JNK) coordinately regulates phosphorylation of p70S6K1 (42-44). JNK is a stress-activated pathway, and its activation directly enhances p70S6K1 phosphorylation and promotes the activation of mTORC1-dependent p70S6K1 (Figure 6) (44). Moreover, the JNK/Bcl-2/Beclin-1 signaling pathway was essential for endoplasmic reticulum stress-induced autophagy in cancer cells (Figure 6), without interaction with p70S6K1 (45-47). It has been reported that EGFR-TKIs (gefitinib and erlotinib) might induce ER stress in lung (48). Accordingly, we supposed that the potential of JNK/Bcl-2/Beclin-1 signaling-mediated autophagy and apoptosis by GW3965 treatment in PC9 cells (Figure 6, Grey lines), which might associate with Akt/mTOR, AMPK and p70S6K1 signaling pathways. All pathways might confer sensitivity to gefitinib-resistant PC9 cells, and were associated with the synergistic effect of GW3965 on overcoming the acquired resistance to gefitinib

in PC9 cell line.

In summary, we confirmed the synergistic effect of LXR ligand GW3965 and gefitinib on the inhibition of PI3K/Akt/mTOR signaling pathway, and on cell apoptosis and autophagy. The synchronicity between AMPK activation and cell apoptosis and autophagy was also observed in our study. Thus, we concluded that the dominant roles of AMPK-ATG1, p70S6K1 and JNK mediated cell autophagy were essential for sensitivity in gefitinib-resistant PC9 cells. In addition, these signaling pathways were associated with the synergistic effect of GW3965 and gefitinib in PC9 cells on overcoming the gefitinib resistance.
